

The same move, in two fields

Multilocus genetics

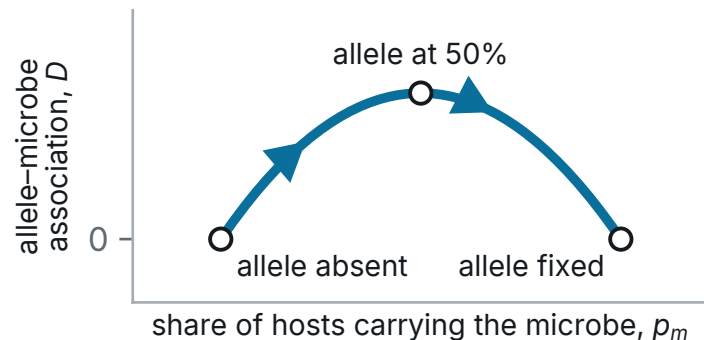

Host-microbe dynamics

The same reduction applies wherever microbes turn over faster than hosts evolve.

In the rescue model

so the variance in host growth rate splits as

$$G_A = (s_g + e p_m)^2 p_g (1 - p_g)$$

$$M_A = (s_m + e p_g)^2 p_m (1 - p_m)$$

$$C_A = 2 (s_g + e p_m)(s_m + e p_g) D$$

p_m and D follow the curve above, so all three depend on p_g alone
