

How do we combine these ingredients to find the signature of host-microbiome interactions?

Not without the background

structure that creates associations by itself

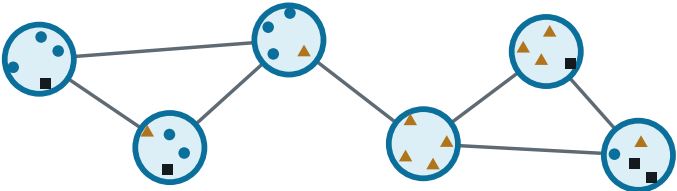

Together they decide how microbiomes are inherited.

where hosts live

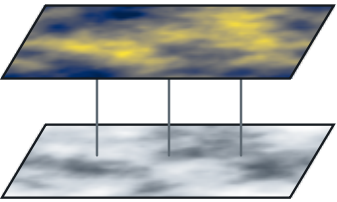

geography: spurious associations

whom they meet: social structure

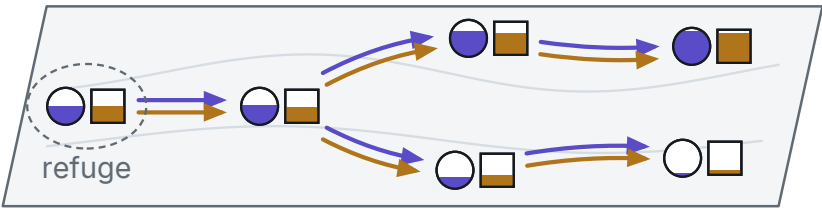

with Aura Raulo and Guilhem Sommeria-Klein

Similarly, for coevolution: how do we account for background selection and shared dispersal history?

background selection

two species spread from one refuge along the same routes

shared dispersal history

their genetic
structure
matches,
**without
coevolving**

fill: allele frequency
